Agent Based Modeling of Pandemic Spread

- **Hypothesis -** Reducing the movement of agents will reduce the infection peak and delay it.
- **Result -** Partially Correct
- **Explanation -** Reducing the movement helped in lowering the infection peak but it did not delay the peak in all the cases.

Interesting Result - This is one of the interesting chart for me as I did not expect average peak to drop from 95 to 16 after changing the movement from 1.0 to 0.1 and I expected the consistent delay as we decrease the movement m, but it was not consistent.

Lesson Learned - Lots of lessons learned actually and some of them are how the movement factor affects the infection spread, why multiple runs are required and single simulation is not enough.
