HW 2 - Agent Based Modeling of Pandemic Spread

[Hypothesis]

(i) How do you expect reducing the agents' movement to change height and timing of the infection peak?

- I am expecting that if agents will move less, the disease will spread slowly.

And total highest number of infected agents will be low and will come later.

(ii) Whether you expect individual simulation runs to look alike and why?

- I do not think that individual simulations will look same and give us same output. One of the main reason I can think is randomness - in positions and in moves.

(iii) Whether you expect the average agent based curves to resemble the SIR curves of the lecture.

- I think the average agent based curves will be similar to the ones we studied in the lectures. Susceptible agents will reduce, infected ones will initially be high but will reduce later, and the recovered ones will also increase.
